*Ladies and Gentlemen,
Dear Colleagues,*

The German IVF-Registry is turning 30!

Not quite four years after the first birth following an IVF-treatment, in the year the first „German IVF-baby“ was born, the then five active centers in Germany joined forces to document their activities in this new and in the eyes of many revolutionary field. They decided to make both their activities and their results accessible to the public. This way however, the Registry not only carried information about the results to scientists and into the interested public, it also transmitted transparency and lead to a less opaque perception of our field – showing that we are by no means secretly working on the creation of a homunculus.

Since 1996, when the results were first published in print, this annual has become a highly important resource for patients, doctors, politicians, as well as journalists. Even the highest courts of justice rely on the results to arrive at their decisions. More than 1.2 million cycles have been documented in our Registry since 1982. Since 1997 more than one million cycles have been recorded electronically – to this day unique and unsurpassed worldwide.

742 treatment cycles were reported in 1982 – in this 2011-edition, the total comes to 80,943 cycles. Yet we should bear in mind that before the introduction of the GMG (health system modernization act) 105,845 had been reported.

While in the year 1982, the average clinical pregnancy rate was 7%, in 2010 it is 29.3% after IVF or ICSI. Just for comparison: the natural conception rate in humans is between 27 to 30% – the rate after ART thus surely a clear indicator for the excellent quality reproductive medicine in Germany stands for.

Due to a variety of societal changes, the percentage of women age 35 and above undergoing IVF or ICSI has risen from 38.7% to 54.4%. Yet the great number of cases in the Registry also justifies the conclusion that in Germany, women between the age of 40 and 42 with good tubal reaction have a mean probability to achieve a pregnancy ranging from 22 to 23%.

Politically relevant is the result that there is no significant difference in the probability for achieving a pregnancy in a 6th cycle over the first three cycles for women under 35. Thus, the assumptions made in 1990 and 2003 – close to no probability at the age of 40 and no significant probability after the 3rd treatment cycle – no longer hold and politics in this country are obligated to react.

For years now, politics and politicians in this country have announced the expansion of financial support for couples suffering from fertility problems. Yet to this day, hardly any support has reached our patients. Instead, they are crushed between the various political fronts. What a disgrace for a country so desperately in need of more children! Only the federal states Saxony, Saxony-Anhalt and, starting in 2013, also Lower-Saxony have picked up on the idea and give financial support to couples, provided they have been living in the respective state and receive treatment there.

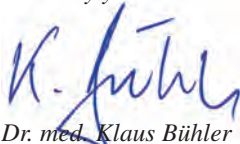

It seems wrong that location is the decisive factor for a couple's rate of co-payment.

A number of statutory health insurance companies have recently started to make use of the „GKV-Versorgungsstrukturgesetz“ by offering special conditions to couples seeking fertility treatment. The resulting reduction of the 50% co-payment is highly appreciated by patients and centers alike.

We are grateful to all who, over the past 30 years, have contributed towards making the German IVF Registry into a world-wide unique and highly respected information resource and quality control instrument. Above all, our gratitude is extended to the teams in the centers for reproductive medicine. Only through their continuous, at time inevitably tedious collection of relevant data, a registry of this magnitude comes to life and is able sustain its outstanding quality. Our gratitude is also extended towards the team at the Ärztekammer Schleswig-Holstein. For the past 15 years, it has handled the registry management as well as the data evaluation in an outstanding manner.

We pay tribute to Professor F. Lehmann for founding the registry in 1982, and to its recent chairmen Professor H. Rjosk and Professor R. Felberbaum. Our recognition and thanks go to the members of the board, the advisory committee, and the board of trustees for their engagement and the spare time sacrificed to make the Registry into what it is today.

Sincerely yours

Dr. med. Klaus Bühler
Chairman

Abstract: The German IVF-Registry (Deutsches IVF-Register, D-I-R) was established in 1982. Its main objective, from the beginning, was to lend transparency and openness to the newly established infertility treatment options.

By 1996 electronic data collection was implemented, allowing the online check for data completeness and plausibility as well as ensuring prospectivity. Since 1997, data entry has to be performed electronically. From 1998, participating in the German IVF-Registry has become mandatory by decree of the German Medical Association.

By the year 2011, the registry comprised 128 centers, with all 128 submitting their data to D-I-R: 80,934 treatment cycles were reported in 2011; 780,922 datasets are plausible, and 67,935 fulfill prospectivity. 53,076 oocyte retrievals led to an IVF or ICSI treatment, and in 48,166 of these “fresh” cycles, an embryo transfer (ET) was performed. In addition to these “fresh” cycles, 19,228 embryo transfers with cryopreserved thawed pro-nucleus-stage oocytes were recorded.

In 2011, the clinical pregnancy rate for IVF is 30.2% and for ICSI 28.3%. Generally we observe that in the data-collection-year the outcome of about 40% of all reported pregnancies is unclear. One year later this figure decreases to about 12.5–15%. From 1997 to 2011, a dramatic reduction of triplets results from the 20% reduction of the number of embryos transferred.

More than one million cycles have been collected since the registry's establishment in 1982 and the births of 171,722 children have been reported to D-I-R since 1997. **J Reproduktionsmed Endokrinol 2012; 9 (6): 456–84.**

■ ART 2011 in Germany: Safe and Successful

In this 30th year after its founding, the German IVF-Registry (Deutsches IVF-Register [D-I-R]) again comprehensively publishes the data collected in the survey of reproductive treatments rendered in Germany in 2011.

A total of 49,696 women had been treated by means of extracorporeal fertilization (Assisted Reproductive Technique – ART) in 2011.

By comparison, 47,159 women had undergone this treatment in 2010.

By the year 2000, the General Directive for Assisted Reproduction ([Muster-] Richtlinie Assistierte Reproduktion) issued by the German Medical Association had been implemented Germany-wide and the participation in the D-I-R Registry was now obligatory for each center. As a consequence, the reported number of treated women dropped to 38,442. However, in 2003, just prior to the inauguration of the Health System Modernization Act (“Gesundheitssystem-Modernisierungsgesetz” [GMG]), the number had risen to 63,111. On an average, each of these women underwent 1.63 treatment cycles.

Plausibility and Prospectivity Remain High

80,943 treatment cycles were documented in the D-I-R Registry in 2011. The checks classified 97.5% as “plausible” already upon entry of the dataset. Thus, all the information requested in the D-I-R questionnaire was considered complete and seemed inherently consistent.

It goes without saying that it is impossible to verify all of the data comprehensively nor can every input error be caught by plausibility checks. Still, for the majority the inherent logic, in particular in reference to other items, can successfully be verified this way. Another key feature of the German IVF-Registry is the „prospective“ data collection: a specific treatment cycle is entered into the system within the first 8 days after the treatment had been initiated. At this point, the result of the treatment is still unclear. This process of continuous and prospective data collection contributes greatly towards data quality. Moreover, the evaluation of the large number of cases allows for reliable conclusions as well as the comparison of treatment strategies.

While plausibility and prospectivity rates had declined for a few years due to

the implementation of different data acquisition solutions, we see an increase to 97.5% and 86.1%, respectively, in 2011. Certainly, the recently introduced software solutions have added to this increase because they facilitate compliance with the criteria.

General Availability of ART Services

In 2011 the number of centers performing extracorporeal fertilization in Germany has increased to 128. We of course see a concentration of centers offering these highly specialized treatments in the cities. However, the list of participants in the back of the yearbook does show that the area-wide and need-based coverage is warranted.

Number of Treatment Cycles Gradually Increases

The steady increase following the dramatic reduction in 2004 can partially be attributed to the clear increase of ICSI (intracytoplasmic sperm injection) treatments. The article on the parameters for sperm analysis (p. 458) uncovers the reasons behind this development. Looking at the European data it becomes quite obvious that the increase is by no means a specifically German trend. ICSI has very noticeably become the treatment of choice.

Contact: Wolfgang Dahncke, Manja Hühstedt, Mirja Wendelken

This article is not peer reviewed.

The average pregnancy rate of 28.7% in so-called fresh-cycles (30.2%/transfer in an IVF-cycle and 28.3%/transfer in an ICSI-cycle) corresponds to the natural monthly fertility rate. Yet, we also see that cryopreservation of PN-cells followed by a thawing- and-transfer cycle has nominally as well and relatively increased considerably during the past five years. In 2006, 9,983 such cycles ($\hat{=}$ 19.9% of all cycles) were performed and in 2011 16,958 ($\hat{=}$ 25%).

Multiple Pregnancies Continually Decrease

The risk of bearing triplets has decreased noticeably over the years. While in 1997 an average of 2.49 (IVF) and 2.56 (ICSI) embryos had been transferred, we see a decline to 1.99 and 2.02 resp. in 2011. This decrease by approximately 20% leads to an 80% drop of triplets in all children born after ART. Comparing the number of multiple births after ART with the total number of multiples recorded by the German Federal Statistical Office shows that the reproductive fertility treatments account for 17.7% of all multiple births (2,101 of a total of 11,838).

Influence of Woman's Age Still Underestimated

For years, the age-related pregnancy and miscarriage rates have been a valuable and effective tool for the information of our patients. In our consultations we still notice a remarkable lack of knowledge about the extent of the reproductive window. Couples are still quite unaware of the continuously diminishing probability per month to achieve a pregnancy after the age of 32–33. In 1996, every third woman undergoing treatment was 35 years and older, in 2011 this applies to more than half of our female patients.

Embryo Quality the Most Crucial Factor

As might be expected, we can very clearly show again this year that the individual pregnancy probability is not only highly age-dependent. The probability also depends to a great degree on embryo quality. Up to the age of 40, transferring more than two embryos of "ideal" quality is of no advantage but on the contrary increases the risk of a higher grade multiple pregnancy – a condition to be avoided at all cost. Although under the present German legal parameters, the

What's New – in Brief The Bottom Line

- 1997 to 2011, a total of 172,993 children have been documented in the registry
- Averaged over all age groups, 36.1% of all embryo transfers in a conventional IVF cycle resulted in a pregnancy – intact ovarian function given
- In an ICSI cycle, in 33.6% of all transfers a pregnancy was achieved
- In a cryopreservation cycle (previously frozen and later thawed egg cells in the pronuclear stage) this probability was 19.7%
- Intact ovarian function given, the 2010 data show that for 23.7% of all embryo transfers a birth was documented
- Every second woman treated in 2011 was 35 years and older. In 1996 – only 15 years ago – this was true for merely every third woman
- The older the woman, the higher the risk of incurring a miscarriage. On the other hand, both egg cell reservoir and egg cell quality decrease with rising age.
- Total probability of pregnancy increases steadily with the number of treatment cycles and according to the number of the embryos transferred
- In comparison with previous years, the multiple birth rate was further reduced. Only 17.7% of all multiples born in Germany in 2011 can be attributed to assisted reproduction treatments (2,101 [D-I-R] of 11,838 (German Federal Office for Statistics)
- International comparison shows that in 2011, couples undergoing ART again have received treatment of outstanding quality
- The bottom line for patients:
 - Increase patients' awareness of the consequences of progressing age on the development of natural fecundity
 - Strive for good timing of the appropriate therapy
 - Don't wait too long and don't give up too soon

elective "single-embryo-transfer" is not an option, we will certainly strive for a further reduction of the rate of multiple pregnancies.

ART is Safe

Children born after ART show no difference in birth weight compared with non-ART children.

In 2011, serious complications during oocyte aspiration were documented in 0.27% of all treatment cases. This clearly indicates that extracorporeal fertilization is a safe method.

Quality of Data Increases Steadily

As was already pointed out earlier, the German IVF-Registry continuously performs quality verification of the reported data. Prospectivity as well as plausibility are checked when the data are first entered. However, in addition a great number of other parameters concerning the individual centers are checked: the number of first introduced and later-on deleted cycles; the ratio of cryo-thawed-

cycles to the total number of fresh-cycles; cycle entry date and possibly a cluster at day 7 or 8; the normal distribution of the recorded duration of pregnancies – to name only a few.

Needless to say, the outcome quality of every center is evaluated as well. Based on close to a hundred items, an individual center profile is created and made available to the center.

In the graphic representation of the percentile curves that contain the results of all centers each center can determine its own position in relation to the others.

Decades ago already, this procedure was used in the German Perinatal Survey and proved highly reliable and effective. In case of extreme deviations, the Data-Management Department informs the Registry's board. According to the statutes, the board members are eligible to directly approach the specific center and request a statement. In addition, the IVF-commissions in the regional State Chambers of Physicians receive those

profiles, this way allowing for regional quality assurance according to the legal requirements.

This bundle of measures supports the high outcome quality in the field of reproductive medicine in Germany and allows for the continuous improvement of our Registry's impressive data quality.

■ Indications for Reproductive Therapies in the Treatment of Male Subfertility Reconsidered

For several years, the number of ICSI-cycles in extracorporeal therapies has steadily increased and is meanwhile exceeding 75%. This trend can neither be explained by a principally better rate of fertilization, nor a higher transfer or pregnancy rate than achieved by a correctly indicated conventional IVF therapy.

Fertilisation Failure is the Least Favorable Treatment Outcome

The data, published in the 2009 year-book already proved that there is an impending fertilization failure of 40% in a classical IVF starting at a sperm density of $< 25 \times 10^6/\text{ml}$ in the native ejaculate and $< 15 \times 10^6/\text{ml}$ after sperm preparation and/or sperm progressive motility $< 20\%$ native and $< 10\%$ after preparation or an overall motility $< 40\%$ native and $< 65\%$ after preparation.

Fertilization failure is by far the least favorable outcome of a therapy cycle since the couple did not even incur the chance of achieving a pregnancy yet lost one of the limited number of cycles granted if insured in the German statutory health insurance system. Therefore, the incidence of fertilization failure should be avoided at all cost.

New WHO Reference Values are Insufficient Predictors for Male Fertility

The reference values recently published by the World Health Organization in the Laboratory Manual for the Examination of Processing of Human Semen (WHO 2010) have led to remarkable confusion in this country since parameters on the 5th percentile are frequently mistaken for the "standard values".

Diversity in appearance of human sperm cells (top: normal shape, center and bottom: abnormal morphology). [Reprint by courtesy of Prof. Dr. Dr. h.c. Hans Wilhelm Michelmann and Dr. Peter Schwartz, Göttingen.]

The reference values published in the 5th edition of the WHO Manual, however, do not lend themselves to the verification of an indication for reproductive treatment nor for the choice of the appropriate reproductive method since they apply to fertile men whose female partners had become pregnant spontaneously within the course of a year.

Commonly, the "normal" range for laboratory parameters is defined as the mean 95% of all values.

Beyond these limits, values for a significantly different population will be found. For sperm analysis parameters, a one-sided reference interval is much more reasonable since very high parameters will not have a negative effect on fertility. For statistical considerations, the 5th percentile was therefore defined as the lower reference value. Thus, 95% of the men who had become fathers had sperm

analyses with semen volumes of $> 1.5 \text{ ml}$, a total sperm count of $> 39 \times 10^6/\text{ml}$, sperm concentration of $> 15 \times 10^6/\text{ml}$, a progressive motility above 32% within an overall motility above 40%. More than 4% were normomorph. All this indicates that the reference limit drawn by the WHO Manual is for systematic-methodological reasons only. As a matter of fact, the WHO Manual explicitly states that it only very marginally touches on fertility. Moreover, in reproductive medicine sperm analyses are normally not performed for men who have only recently become fathers but rather for men in involuntarily childless couples.

Normal Sperm Parameters do not Prove Male Fertility

Arguments are provided by a prospective Dutch multicenter study on the chances of spontaneous conception in subfertile couples, lacking a relevant female sterility factor. With 3,345 subjects in the study's database, it nearly approximates the WHO collective. From an extended analysis drawn from the study we know that even with sperm concentrations above $40 \times 10^6/\text{ml}$ and an ideal progressive motility of 50%, the probability to conceive spontaneously within one year is at best 65%. Despite seemingly "normal sperm analysis parameters", fertility of these men compared to proven fertile men was reduced to at least 50%.

Based on the lower limiting values of the "old" WHO 1999 (sperm concentration of $20 \times 10^6/\text{ml}$, 25% forward progression), fertility is reduced to less than a quarter. Relative to the 5th percentile of the WHO 2010, the probability of reaching an ongoing stable pregnancy within one year is only 31.53%. This means that 70% of the couples with women not showing a relevant fertility-related factor will not get pregnant for another year. The rate for spontaneous conception per cycle is a mere 3.11%. Fertility of these men is reduced to less than 1/8th of the normal rate.

Duration of Subfertility as Indicator for ART

Sperm analysis thus discloses the degree of fertility reduction in men in subfertile partnerships but lacking a relevant female sterility factor. Since in this collective even "ideal values" do not exclude

the possibility of male subfertility, indication for reproductive treatment is given and can therefore be deducted from the mere duration of involuntary childlessness. The choice of treatment then depends on the results of the sperm preparation and forward progression count. This way, and only this way, the risk of incurring a complete or incomplete fertilization failure can be reduced to a minimum. As can be seen from the current as well as past yearbooks, German IVF-centers have been exemplary in doing so.

References: Please inquire relevant references with the office of the D-I-R Registry.

■ IVF-Labs – Where are we Headed

What the future in our IVF-labs might hold in store for us can be viewed from various angles: what will be new in the future but also where we are headed!

Let Us First Dwell on the Past

Recent introductions into our labs include: new culture media, especially for day-5-culture, optimized techniques for the vitrification of oocytes and embryos, smaller incubators and reduced oxygen atmosphere, quality management lead-

ing to certified and accredited labs. Here and there pregnancy rates might have increased due to these innovations – the big breakthrough, however, was not among them.

If future development is seen under the aspect of success rates, then the major benefit – from the patients' point of view – will certainly lie in the improvement of lab quality in centers with low success rates. In the context of global success rates of 20–25% per treatment cycle we need to acknowledge that according to the 2010 D-I-R figures, 40 of the 100 largest IVF-centers – after all – display a pregnancy rate per transfer of under 25%. A fact that cannot be neglected since new lab techniques and sophisticated procedures do require a certain quality level in order to allow for their integration into the routine and result in the expected added gain.

Morphokinetics Increasingly Important

The challenge of identifying those embryos with the highest implantation potential in a treatment cycle is still top of the list of all future aspects. In the years to come, morphokinetics, i. e. the morphological assessment of embryos over time, will play an increasingly dominant role. If supplemented with simple and physiologically significant diagnostic methods – apart from array-CGH mainly

with improved metabolomic concepts – and in combination with vitrification, the elective “single embryo transfer” will inevitably prevail, thus leading to a further reduction of the rate of multiples.

Economics Enters the IVF-Lab

The future in and of the IVF-Labs however will also be determined by economic aspects. Internationally, lab conglomerates have been entering the scene and the acquisition of IVF-centers by investors is by no means something new. Inevitably this development will lead to new concepts: central IVF-laboratories and the standardized critical evaluation and selection of the embryos to be transferred via electronic communication systems will enter our every day lives.

Many interesting challenges lie ahead, challenges that require a certain openness to change as well as reconsideration of traditional approaches.

■ Acknowledgements

Our sincere gratitude goes to Prof. Dr. rer. nat. Markus Montag, Heidelberg, for his invited article “IVF-Labs – Where are we Headed”. We thank Monika Uszkoreit for her translation of the German texts into English.

Outcome of ART 2011

Baby-take-home rate ***		16.72 ¹		17.30 ¹		21.27 ¹		11.23 ¹
		17.73 ²		19.19 ²		23.97 ²		12.61 ²

Prospectively and retrospectively collected data were used.

*) Number of cycles, in which an induced abortion/fetal reduction was documented. Detailed data cannot be given. Number of embryos are given in brackets.

**) Number of dead newborns corresponding to the number of children

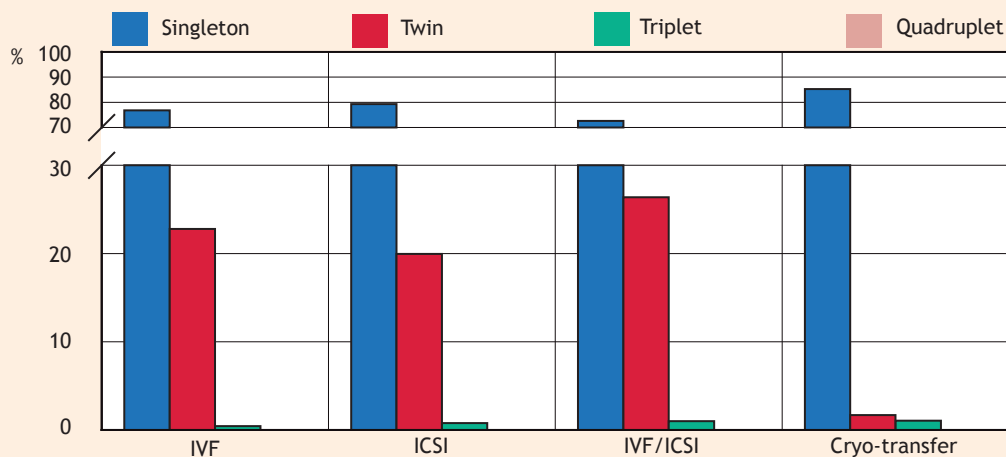

***) Number of deliveries in correlation to the number of treated cycles given in percent.

1) Total number of treatment cycles reduced for those cycles with unknown pregnancy outcome.

2) For cycles with unknown pregnancy outcome the probable rate for deliveries was calculated (delivery per pregnancy) and added to the reported number of deliveries.

Delivery rate/transfer for patients with 2 embryos transferred and at least 2 ZPN stages in abundance: IVF 23.30 %, ICSI 23.81 %, IVF/ICSI 24.87 %

Multiple deliveries 2010

Prospectively and retrospectively collected data were used.

Only prospectively collected data were used.

Average age of women and men

1997 - 2011 - IVF, ICSI, IVF/ICSI

Age in years

Men
Women

● : Mean
I : 95 % confidence interval (e.g. in 1997, the CI for women with a mean age between 32.51 and 32.65 years shows a probability of 95%)

n = 663,076 cycles with plausible age documentation

Prospectively and retrospectively collected data were used.

Duration of childlessness at the time of first treatment

1997 - 2011 IVF, ICSI, IVF/ICSI

Years [Duration of childlessness at the time of first treatment]

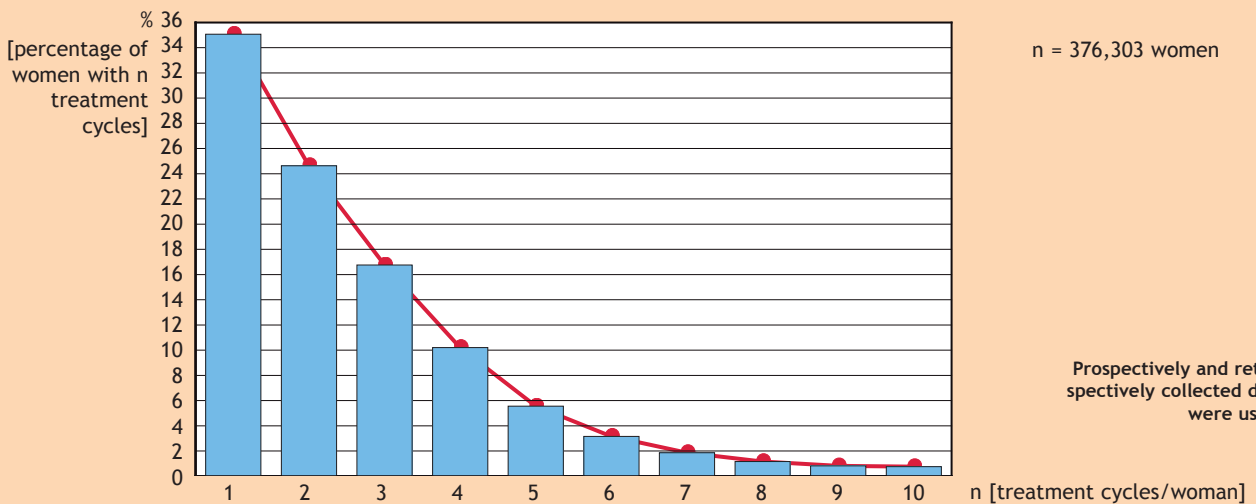

n = 321,588 first treatment cycles with known duration of infertility

Prospectively and retrospectively collected data were used.

Number of treatment cycles per woman

1997 - 2011 IVF, ICSI, IVF/ICSI, cryo-transfer

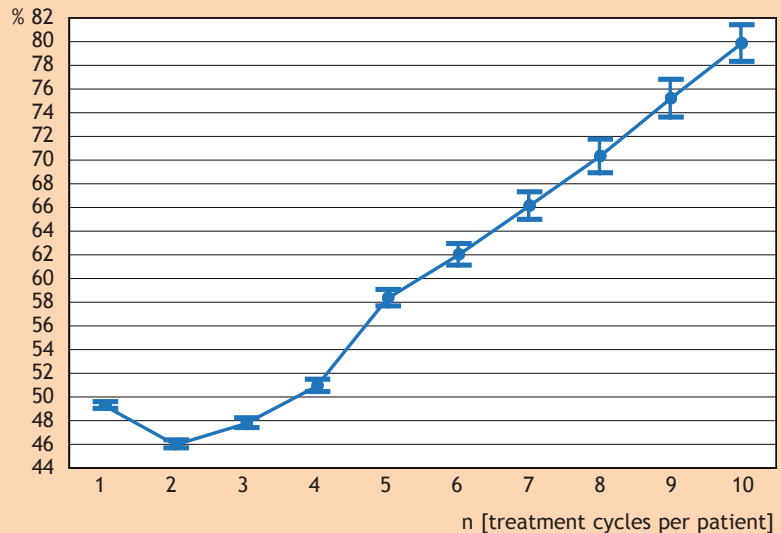

Total probability per woman for pregnancy

1997 - 2011 IVF, ICSI, IVF/ICSI, cryo-transfer

Total probability per woman for pregnancy as a function of the number of treatment-cycles

n = 376,303 women

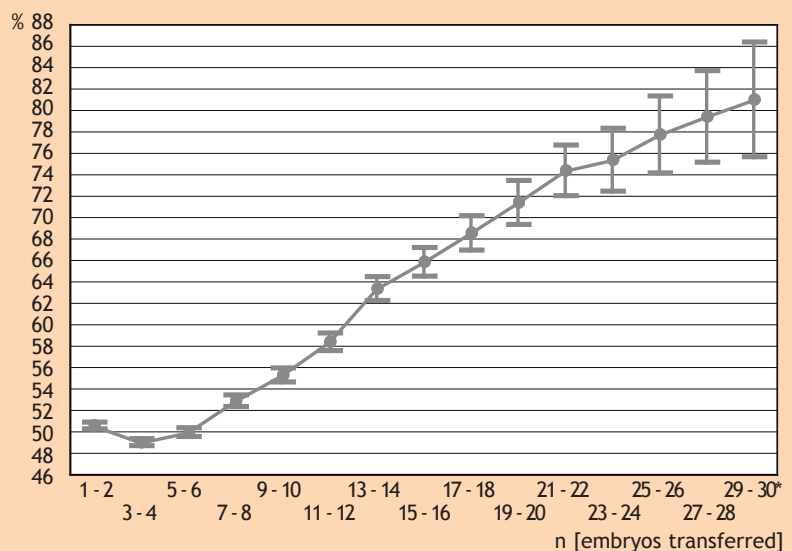

In 10 treatment cycles (n = 1,755) there is an 80% probability for a pregnancy.

Total probability per woman for pregnancy as a function of the number of the sum of embryos transferred

n = 376,303 women

With 29-30 embryos transferred, there is an 81% probability for a pregnancy.

Prospectively and retrospectively collected data were used.

Clinical pregnancy rate as a function of the number of oocytes retrieved and the duration of embryo culture

2007 - 2011 IVF, ICSI, IVF/ICSI

Clinical pregnancy rate (Clin. PR/ET)

Number of oocytes retrieved

n = 208.620 treatment cycles (the 5 days-culture has been increasing from 15 % to 21 % in the period mentioned above)

Note: The higher pregnancy rate in 5 days-cultures can be explained by the higher number of oocytes retrieved.

Prospectively and retrospectively collected data were used.

All children born 1997 - 2011 prospective and retrospective data

IVF, ICSI, IVF/ICSI

Only prospectively collected data were used.

Therapy decisions against outcome of previous treatment cycle

1997 - 2011, IVF, ICSI, IVF/ICSI, cryo-transfer

Note: A previous ART-pregnancy increases the probability for consecutive pregnancies.

- number of women getting pregnant in the n-th treatment cycle
- number of women *not* getting pregnant in the n-th treatment cycle
- women not undergoing another treatment cycle (● end point)
